Timing and Structure
Michaelmas term. 100% coursework

Prerequisites
3B2 useful

Aims
The aims of the course are to:

- Introduce students to the principles and practice of computation and sensing systems that interact with the physical world.

Objectives
As specific objectives, by the end of the course students should be able to:

- Define the role of uncertainty in measurements of physical signals and quantify measurement uncertainty for a given sensing system.
- Evaluate energy use in an embedded system using in-system current monitors.
- Define the role of noise in both measurements and displays and identify appropriate metrics to use in quantifying noise for a given design.
- Design communication subsystems and the required electrical circuit support between a collection of I2C- or SPI-interfaced sensor integrated circuits and an ARM Cortex-M0 microcontroller.
- Numerically quantify measurement uncertainty and noise in outputs given a system design.
- Recall and explain the interaction between displays and the human visual system.
- Design modifications to sensing, communication, and display systems to improve their energy efficiency.
- Design the logical organization and required firmware for new systems built around an ARM Cortex-M0 microcontroller, and sensors or displays connected via I2C and SPI communication interfaces.

Content
The module will introduce students to the principles underlying sensor operation, signal acquisition, the role of measurement uncertainty and noise, common sensor communication interfaces and how they interact with modern embedded systems. This exploration of output systems will be built on a study of the principles of operation of OLED displays and how the flexibility of the human visual system enables interesting circuit- and algorithm-level techniques to reduce display power dissipation.

Preliminary Syllabus

Lecture 1: System overview of sensing, computation, I/O, and displays in embedded systems; interpreting device and system datasheets. At the end of this lecture, students should be able to: enumerate the important components in an embedded system design; read and interpret the datasheet for a component in a system or for an entire system; propose and design changes to a system to extend its uses.

Lecture 2: Precision, accuracy, reliability, and measurement uncertainty. Noise sources in analog and digital systems; role of signal gain and restoring logic. At the end of this lecture, students should be able to: define precision, accuracy, reliability, and measurement uncertainty; analyze a system design and quantify these properties for a design's components; enumerate the sources of noise and measurement uncertainty in analog and digital systems; propose design changes to improve the robustness of systems to noise.

Lecture 3: Embedded I/O interfaces: I2C, SPI, I2S, I3C, MIPI DSI, and MIPI CSI. At the end of this lecture, students should be able to: enumerate the differences between the common embedded wired communication interfaces; select and substantiate a choice for an interface for a given design problem.

Lecture 4: C and assembly programming for embedded systems. At the end of this lecture, students should be able to: implement firmware that runs in the absence of an operating system and which contains a mixture of C and ARM assembly code.

Lecture 5: Embedded library and OS support overview; ARM Mbed OS API and TI-RTOS. At the end of this lecture, students should be able to: design the firmware for an embedded sensing and computing problem using Mbed OS API calls for actions such as I/O.

Lecture 6: Case study.

Lecture 7: Field-programmable gate arrays in low-power embedded systems; Verilog overview. At the end of this lecture, students should be able to: describe and explain the basic architecture of FPGAs; use their understanding of the Verilog hardware description language and FPGA synthesis tools to modify an existing Verilog design.

Lecture 8: Human color vision perception and its interaction with OLED displays: Their structure, interfaces, and techniques for energy-efficiency. At the end of this lecture, students should be able to: enumerate the properties of OLED displays; propose changes to existing system designs that use OLED displays in order to improve their energy efficiency; enumerate the basic properties of human color vision that have a bearing on the design of displays for embedded systems.

Lecture 9: Physical invariants in embedded systems. At the end of this lecture, students should be able to: define physical invariants in the context of a sensor-driven system; apply concepts from Lagrangians, Hamiltonians, the Euler-Lagrange Equations, Noether's theorem, and recent research on inferring Lagrangians and Hamiltonians from sensor data to embedded systems designs.

Lecture 10: Wireless communications using Bluetooth, 802.15.4/Zigbee, and LoRa; Bluetooth HCI interface. At the end of this lecture, students should be able to: enumerate the differences between the major low-power radio interfaces available for embedded or Internet-of-Things systems; propose energy-efficient choices for a wireless sensing system design given the application's design constraints.

Lecture 11: Schematic capture and basic printed circuit board layout using Eagle. At the end of this lecture, students should be able to: create a design ready to be submitted for manufacturing (Gerber files) using the Eagle schematic capture and printed-circuit-board layout tools.

Lecture 12: Designing new embedded systems to solve a specified application need. At the end of this lecture, students should be able to: propose an architectural design comprising sensing, computation, communication, and display to address a given application need, with the design implementable within the limitations of schematic capture and printed-circuit-board layout tools such as Eagle.

## Coursework

After successfully completing this exercise, students should be able to:

- Use the supplied FPGA tools to map an existing Verilog hardware design to the iCE40 FPGA.
- Modify an existing Verilog hardware design that harnesses hard-macros on the iCE40 FPGA and map/evaluate the design on the FPGA evaluation board.

### Coursework activity #5: Project interim report

Present progress made towards final project goals, evaluate lessons learned so far, and obtain feedback and guidance on necessary plan adaptation.

**Learning objectives:**

- Identify and present progress made towards final project.
- Identify and present potential challenges and propose necessary changes to project plan.

### Coursework activity #6: Project concept, design, implementation, and final report

Present the problem addressed, approach employed, system implemented, and system evaluation.

**Learning objectives:**

- Identify an interesting and important engineering challenge that can be solved using a combination of embedded sensing, embedded computation, and possibly displays and communication.
- Design an embedded computing system that address the engineering challenge.
- Prototype an embedded system design using a combination of sensors, microcontrollers, communication, displays, or FPGAs using the tools provided in the course kit, and potentially design a custom PCB implementing the design.
- Quantitatively evaluate an embedded sensing and computation system in terms of its time efficiency (performance), energy efficiency (battery life), and measurement and data processing accuracy.

## Booklists

The following books are relevant to the material in the course and will all be available from the Engineering Library.

**Examination Guidelines**

Please refer to [Form & conduct of the examinations](http://teaching.eng.cam.ac.uk/content/form-conduct-examinations) [2].
