## Revision questions.

i) Sketch the electric field lines and direction for the following charged objects:
a) A point charge of magnitude $+Q C$
b) A line of static charge on a wire of density $-\rho_{l} \mathrm{Cm}^{-1}$
c) A plane of static charge of density $+\alpha \mathrm{Cm}^{-2}$
d) A hollow metal sphere with total charge $+Q$.
ii) A fixed point charge of +1 C is a distance of 10 cm away from a second fixed point charge of -1 C . Sketch a diagram showing the force acting on the charges and calculate the magnitude of this force. Comment on the magnitude of your answer.
iii) A parallel plate $10 \mu \mathrm{~F}$ capacitor is charged to a voltage of 10 V by a battery. The battery is then removed and the capacitor is connected a $10 \Omega$ resistance. Sketch a plot of how the voltage across the capacitor changes with time after the resistor has been connected. Explain where the original charge on the capacitor goes to.
iv) Two parallel straight wires of length $1 \mathrm{~m}, 10 \mathrm{~cm}$ apart, are both carrying a current of 1A. Calculate the force between the two wires. Comment on the importance of the direction that the currents are traveling.

Straightforward questions are marked with $a+$
More difficult questions are marked with $a^{*}$

1. Two identical glass spheres of radius $r$ and mass $m$ and charge $+Q$ are suspended as shown in Fig 1 on two threads of negligible mass and length $l$. Show that at equilibrium the inclination angle $\theta$ to the vertical is given by:

$$
Q^{2}=16 \pi \varepsilon_{0} m g(l+r)^{2} \sin ^{2} \theta \tan \theta
$$

If the angle $\theta$ is very small simplify the above expression to give $\theta$.

Fig 1

Optional (discuss with your supervisor) - for a more challenging problem try it with 3 equal charged spheres, state any assumptions made.
2. Three fixed point charges are placed on a 2 dimensional $(x, y)$ plane measured in millimetres, with a central origin at point $(0,0)$. The value and position of each charge are as follows:

Charge A: 100 nC at position $(0,1)$
Charge B: -120 nC at position $(1,0)$
Charge D: 150 nC at position $(-1,-1)$
Sketch the plane showing each charge and calculate the magnitude and direction of the electric field E at the position $(2,2)$. Discuss with your supervisor what happens initially and some time interval later if the charges were free to move?
$3^{+}$. Explain why the electric field between a pair of parallel conducting plates is always uniform when there is a potential difference between them of $V$ and a surface area $A$ that is much larger than their separation $d$. Show that the total electric field is given by $E=V / d$. A voltage of 120 volts is maintained between a pair of $50 \times 50 \mathrm{~mm}$ plates with a separation of 20 mm . Calculate the electric field and the potential difference at a point midway between the plates. What is the capacitance of the capacitor?
4. A capacitor consists of two conducting plates of identical areas large enough compared with their spacing for edge effects to be neglected. The plates are 0.1 mm apart and the space between them is partially filled with a polythene sheet of thickness 0.09 mm , relative permittivity 2.25 and breakdown strength of $30 \mathrm{MVm}^{-1}$. Assuming that the breakdown strength of air is $3 \mathrm{MVm}^{-1}$, calculate the maximum voltage which can be applied to the capacitor. What is the maximum voltage if the polythene sheet completely fills the space between the plates?
5. An infinitely long wire of radius $r_{0}$ has a static charge density of $\rho_{l} \mathrm{Cm}^{-1}$ along its length. Use Gauss' law to find the electric field $E$ at a distance $r$ away from the wire. Calculate the electric field for $r<r_{0}$ stating any assumptions made. How would the electric field vary if the wire was surrounded by a dielectric gas with a relative permittivity of $\varepsilon_{r}$ instead of air? What happens if $\varepsilon_{r}=f(r)$ ?

6*. Consider the Fig 2 below which is a sketch cross section of an inkjet printer with drops of conducting ink leaving the nozzle N at an electrostatic potential $V$ with respect to the casing C , and with an exit velocity $4 \mathrm{~ms}^{-1}$ in the negative $y$ direction. A constant electrostatic potential difference is applied between the accelerator plates A and B with A being 1500 V positive with respect to B . Describe qualitatively the motion of a drop of ink for the case where it leaves the nozzle with an electrostatic potential of +30 V with respect to the casing C. [Hint: The capacitance of a sphere of radius $d$ is $4 \pi \varepsilon_{0} d$, for optional work use Gauss' law to prove it!]

Calculate the magnitude of the electrostatic force acting on a droplet of diameter 70 microns while it is passing through the region between the plates $A$ and $B$. What is the approximate direction of motion of the droplet, with density $1000 \mathrm{kgm}^{-3}$, after it leaves the region between the plates A and B ? How would the direction change if the droplet diameter were to be doubled?

Fig 2.
$7^{+}$. A long thin copper wire of 1 m length and cylindrical cross section with a radius of 1 mm has an applied potential difference across it of 1 V . Calculate the resistance and current density within the wire. If the wire was in fact a hollow tube cross section with an inner radius $r$ and an outer radius 1 mm sketch a plot of how resistance and current density vary as a function of $r$ from 0 to 0.95 mm .
8. A high voltage direct current transmission line consists of two thin parallel conducting wires, each of radius $a$, placed with their axes distance $2 s$ apart, as shown in cross section in Fig. 3 below, where $s \gg a$. The current is 500 A , equal and opposite in the two wires and uniformly distributed over the conductor cross sections. The separation between the conductors is $2 s=80 \mathrm{~mm}$. Sketch the lines of magnetic flux density and calculate the force/unit length between the conductors.

Fig. 3

## Answers

1. $\theta=\sqrt[3]{\frac{Q^{2}}{16 \pi \varepsilon_{0} m g(l+r)^{2}}}$
2. $1.3 \angle-26 \times 10^{8} \mathrm{Vm}^{-1} \quad(1.17-0.58 j) \times 10^{8} \mathrm{Vm}^{-1}$
3. $\mathrm{E}=6 \mathrm{kV} \mathrm{m}^{-1}, \mathrm{~V}=60 \mathrm{~V}, \mathrm{C}=1.1 \mathrm{pF}$
4. $\mathrm{V}=150 \mathrm{~V} ; \mathrm{V}=3000 \mathrm{~V}$.
5. $\quad 0 \leq r<r_{0} \quad E=0, \quad r_{0} \leq r<\infty \quad E=\frac{\rho_{l}}{2 \pi \varepsilon_{0} r}, \quad D=\varepsilon_{0} \varepsilon_{r} E, E=\frac{\rho_{l}}{2 \pi \varepsilon_{0} \varepsilon_{r} r}$
6. Force $=1.8 \times 10^{-8} \mathrm{~N}$, angle $10^{\circ}$ with respect to the y axis, $2.5^{\circ}$ when diameter doubled
7. $5.8 \times 10^{7} \mathrm{Am}^{-2}, 5.5 \mathrm{~m} \Omega$
8. $\quad 0.625 \mathrm{Nm}^{-1}$
