**You may not start to read the questions  
printed on the subsequent pages of this  
question paper until instructed that you

- 1 (a) Derive the Simple Radial Equilibrium equation (SRE)

$$\frac{dh_0}{dr} - T \frac{ds}{dr} - V_x \frac{dV_x}{dr} = \frac{V_\theta}{r} \frac{d(rV_\theta)}{dr}$$

from the momentum equation in the radial direction:  $\rho V_\theta^2 / r = dp / dr$ . State all the assumptions involved in your derivation. [20%]

- (b) Give a physical explanation for each term in the Simple Radial Equilibrium equation derived in (a). What additional assumptions are required to further reduce the equation to a relationship between the axial velocity distribution in the radial direction and the vortex distribution:

$$-V_x \frac{dV_x}{dr} = \frac{V_\theta}{r} \frac{d(rV_\theta)}{dr} \quad [20\%]$$

- (c) For a given vortex distribution at a certain axial location, the simplified SRE in part (b) above can be integrated to give the  $V_x$  distribution at this location. Describe how the integral constant is determined. [10%]

(d) For a low hub-to-tip ratio free vortex design turbine stage with cylindrical endwalls, the flow through the stage can be assumed to have parallel streamlines. At the inlet of the stage the flow properties are uniform. Downstream of the stator the radial distributions of static pressure and density follow the relation:  $p(r) / p_h = (\rho(r) / \rho_h)^\gamma$ , where  $\gamma$  is the ratio of specific heat capacities and the subscript  $h$  denotes the location on the hub. Discuss the applicability of the simplified SRE derived in part (b) at the exit of the stator row and derive an expression for the radial distribution of velocity. [25%]

- (e) It is found that in reality the velocity distribution behind the stator does not follow the analytical prediction and that the stage loss is high. Discuss possible causes for this and suggest what change(s) to the stator could be made to improve the design. [25%]

2 (a) A two dimensional section of a transonic air compressor rotor with upstream relative Mach number 1.25 produces a static pressure ratio  $p_2 / p_1 = 1.8$ , of which 75% is estimated to be due to shock compression ( $(p_2 / p_1)_{shock} = 1.6$ ) and the remaining 25% due to diffusion downstream of the shock. ( $\gamma = 1.4$  for air.)

(i) Assuming that there is negligible flow turning from the upstream to the passage shock, sketch a possible blade profile and shockwave pattern for the section. Discuss quantitatively whether the main passage shock is normal or oblique with the help of the Engineering Data Book provided. [15%]

(ii) Estimate the specific entropy production,  $\Delta s$ , due to the shockwave. [15%]

(iii) Assume the specific entropy produced in this blade section due to the viscous drag force equals that due to the shockwave estimated in part (ii), i.e.,  $\Delta s_{total} = 2\Delta s_{shock}$ . Estimate the isentropic efficiency of this blade section. Comment on your result. [20%]

(iv) Estimate the loss of stagnation pressure ratio of the blade section due to the production of entropy. Comment on the validity of your estimation in relation to the total entropy production and compare with the estimate of isentropic efficiency in part (iii). [20%]

(b) As exit Mach number increases beyond sonic condition for a transonic turbine blade, the actual loading can still increase but the flow turning reduces.

(i) With the help of a sketch, explain why this is so. [15%]

(ii) Describe the limit loading condition for turbine blades. A transonic turbine blade section has exit metal angle of  $62^\circ$  and it reaches the limit loading condition with an exit Mach number of 1.75. Calculate the deviation angle at this condition. [15%]

3 (a) (i) Explain the causes of secondary flow and suggest reasons why secondary flow might be expected to increase blade row losses. [30%]

(ii) Sketch loss coefficient contours at blade row exit for an axial flow turbine and for an axial compressor, both with significant secondary flow. Explain any differences between the two sketches. [20%]

(iii) Suggest how a low aspect ratio turbine stator could be redesigned so as to reduce secondary flow. [20%]

(b) (i) With reference to the short-comings of other methods, explain the dominance of Euler / Navier-Stokes methods for turbomachinery blade design. Why is the finite-volume approach preferred to the finite-difference technique for this application? [20%]

(ii) Comment on the most significant source(s) of errors / inaccuracies that Euler / Navier-Stokes methods for turbomachinery blade design may have. Suggest how they might be improved. [10%]
